

## defining semantics for complex systems part 2: semantics

Pieter Koopman, Rinus Plasmeijer

Radboud University Nijmegen  
The Netherlands

CEFP 2009: semantics

### syntax & semantics

- the **syntax** tells what is allowed to write in a (programming) language
  - exp = var | num | exp + exp | exp - exp | exp \* exp
  - var = char alpha\*
  - num = [-] digit+
  - e.g. x + 32 is allowed
  - fac 5 is not allowed
- the **semantics** tells what valid sentences mean
  - we are not interested in the semantics of invalid sentences ( not error, undefined, ..)
  - if we know that  $x \mapsto 10$  (x has the value 10), the expression  $x + 4 * 8$  has value 42
  - fac 5 has no value in this language

2

CEFP 2009: semantics

### different kinds of semantics

- **operational semantics**:  
how has the value of a sentence to be computed
  - hides details like storage allocation
  - **structural operational semantics (small step)**  
focus on individual computation steps
  - **natural semantics (big step)**  
hides more details, computes values in one go
- **denotational semantics**:  
gives the value of constructs without worrying how it has to be obtained
- **algebraic semantics**:  
gives algebraic properties of sentences
  - not necessarily complete

3

CEFP 2009: semantics

### semantics for imperative language

- consider the very simple language While
  - v a variable
  - n a number
  - a = v | n | a + a | a - a | a \* a
  - b = TRUE | FALSE | a = a | a < a | ¬ b | b && b
  - S = x := a | skip | S ; S | if b S else S | while b S
  - for instance a statement to compute factorial of 4:
 

```
x := 4;
y := 1;
while (x>1)
( y := y*x;
  x := x-1
)
```

4

CEFP 2009: semantics

### the state in semantics

- in order to compute values we need to know the values of variables
- we store values in a function called **state**:  
state : Variable  $\rightarrow$  Integer
- the state can be updated:  
[x  $\mapsto$  v] s is the state that maps variable x to value v and all other variables to the value in s:  
([x  $\mapsto$  v] s) x = v  
([x  $\mapsto$  v] s) y = s y, if x  $\neq$  y

5

CEFP 2009: semantics

### the semantics of arithmetic expressions

- use Scott brackets, [ and ], to indicate a pattern math on syntax elements in an operational semantics

$$\mathcal{A} : a \rightarrow \text{State} \rightarrow \text{Number}$$

$$\mathcal{A} [ n ] s = \mathcal{N} [ n ] \quad \text{number}$$

$$\mathcal{A} [ v ] s = s v \quad \text{variable}$$

$$\mathcal{A} [ a_1 + a_2 ] s = \mathcal{A} [ a_1 ] s + \mathcal{A} [ a_2 ] s$$

$$\mathcal{A} [ a_1 - a_2 ] s = \mathcal{A} [ a_1 ] s - \mathcal{A} [ a_2 ] s$$

$$\mathcal{A} [ a_1 * a_2 ] s = \mathcal{A} [ a_1 ] s \times \mathcal{A} [ a_2 ] s$$

syntax      mathematical operation

6

CEFP 2009: semantics

### executable operational semantics

- for a functional programmer:

$$\mathcal{A} : a \rightarrow \text{State} \rightarrow \text{Number}$$

$$\mathcal{A} [ n ] s = \mathcal{N} [ n ]$$

$$\mathcal{A} [ v ] s = s v$$

$$\mathcal{A} [ a_1 + a_2 ] s = \mathcal{A} [ a_1 ] s + \mathcal{A} [ a_2 ] s$$

$$\mathcal{A} [ a_1 - a_2 ] s = \mathcal{A} [ a_1 ] s - \mathcal{A} [ a_2 ] s$$

$$\mathcal{A} [ a_1 * a_2 ] s = \mathcal{A} [ a_1 ] s \times \mathcal{A} [ a_2 ] s$$

pattern match: hence a data structure

a function

7

CEFP 2009: semantics

### representation of expressions

the grammar	the data type
a	:: AExpr
= v	= Int Int
n	Var Var
a + a	(+.) infixl 6 AExpr AExpr
a - a	(-.) infixl 6 AExpr AExpr
a * a	(*.) infixl 7 AExpr AExpr
	:: Var := String

dot to avoid name conflicts

infix constructor with binding power

8

CEFP 2009: semantics

## semantic functions for arithmetic expressions

<b>Scott brackets</b>	<b>Clean</b>
$\mathcal{A} : a \rightarrow \text{State} \rightarrow \text{Number}$	$A :: \text{AExpr State} \rightarrow \text{Int}$
$\mathcal{A} [n] s = \mathcal{N} [n]$	$A (\text{Int } i) \quad s = i$
$\mathcal{A} [v] s = s v$	$A (\text{Var } v) \quad s = s v$
$\mathcal{A} [a_1 + a_2] s$	$A (x +. y) \quad s = A x s + A y s$
$= \mathcal{A} [a_1] s + \mathcal{A} [a_2] s$	$A (x -. y) \quad s = A x s - A y s$
$\mathcal{A} [a_1 - a_2] s$	$A (x *. y) \quad s = A x s * A y s$
$= \mathcal{A} [a_1] s - \mathcal{A} [a_2] s$	
$\mathcal{A} [a_1 * a_2] s$	
$= \mathcal{A} [a_1] s \times \mathcal{A} [a_2] s$	

see Nielson & Nielson 1992  
only the syntax is improved

9

## main idea

- semantics  $\approx$  interpreter that focuses on clarity rather than efficiency

CEFP 2009: semantics

## evaluating the FPL approach

<b>disadvantages</b>	<b>advantage</b>
<ul style="list-style-type: none"> <li>• less abstract/mathematical</li> <li>• harder to reason about</li> <li>• nontermination is a problem</li> <li>• semantics inherits from embedding programming language</li> </ul>	<ul style="list-style-type: none"> <li>• compiler checks proper use of identifiers and types</li> <li>• we can execute the semantics               <ul style="list-style-type: none"> <li>• simulate for validation</li> <li>• model based testing of properties</li> </ul> </li> <li>• nontermination always requires separate attention</li> <li>• the price to be paid is rather small</li> </ul>

11

CEFP 2009: semantics

## Boolean expressions

<b>grammar/data type</b>	<b>semantic function</b>
$:: \text{BExpr}$	$B :: \text{BExpr State} \rightarrow \text{Bool}$
$= \text{TRUE}$	$B \text{ TRUE} \quad s = \text{True}$
$  \text{FALSE}$	$B \text{ FALSE} \quad s = \text{False}$
$  (=.) \text{ infix } 4 \text{ AExpr AExpr}$	$B (x =. y) \quad s$
$  (<.) \text{ infix } 4 \text{ AExpr AExpr}$	$= A x s == A y s$
$  \sim. \text{ BExpr}$	$B (x <. y) \quad s$
$  (&&.) \text{ infix } 3 \text{ BExpr BExpr}$	$= A x s < A y s$
	$B (\sim. \text{ exp}) \quad s$
	$= \text{not } (B \text{ exp } s)$
	$B (x \&\&. y) \quad s$
	$= B x s \&\& B y s$

12

## semantic domains

- in this way the semantics of `While` inherits the numbers and `Booleans` of `Clean`
- if this would be undesirable we can always introduce a new type and associated operators

$:: \text{TruthVal} = \text{TT} \mid \text{FF}$

$B :: \text{BExpr State} \rightarrow \text{Bool}$

$B \text{ TRUE } \quad s = \text{True}$

$B \text{ FALSE } \quad s = \text{False}$

$B (x \ \&\&. \ y) \ s$

$\quad = B \ x \ \text{env} \ \&\& \ B \ y \ \text{env}$

..

$B :: \text{BExpr State} \rightarrow \text{TruthVal}$

$B \text{ TRUE } \quad s = \text{TT}$

$B \text{ FALSE } \quad s = \text{FF}$

$B (x \ \&\&. \ y) \ s$

$\quad | \ B \ x \ \text{env} == \text{TT} \ \&\& \ B \ y \ \text{env} == \text{TT}$

$\quad = \text{TT}$

$\quad = \text{FF}$

..

better: define an instance of `&&` for `TruthVal`

CEFP 2009: semantics

## the state

- (at least) two possibilities

➤ data structure, e.g.  $[(\text{Var}, \text{Int})]$

- needs separate lookup and store functions
- easy to compare states

➤ function,  $:: \text{State} ::= \text{Var} \rightarrow \text{Int}$

- close to the mathematical semantics
- hard to compare states

- we will use the function approach

$\text{emptyState} :: \text{State}$

$\text{emptyState} = \lambda x \rightarrow 0$

$(\mapsto) \text{infix} :: \text{Var Int} \rightarrow \text{State} \rightarrow \text{State}$

$(\mapsto) \ v \ i = \lambda \text{env} \ x \rightarrow \text{if } (x == v) \ i \ (\text{env } x)$

14

CEFP 2009: semantics

## statements in `While`

### syntax

$S$

$= x := a$

$| S ; S$

$| \text{skip}$

$| \text{if } b \ S \ \text{else } S$

$| \text{while } b \ S$

### data structure

$:: \text{Stmt}$

$= (:=.) \text{infix } 2 \ \text{Var} \ \text{AExpr}$

$| (:. ) \text{infixr } 1 \ \text{Stmt} \ \text{Stmt}$

$| \text{Skip}$

$| \text{IF } \text{BExpr} \ \text{Stmt} \ \text{Stmt}$

$| \text{While } \text{BExpr} \ \text{Stmt}$

15

CEFP 2009: semantics

## operational semantics of statements

- big step operational semantics:

➤ describe how the result must be calculated

➤ in one go to the result: a new state

$\text{ns} :: \text{Stmt State} \rightarrow \text{State}$

$\text{ns } (v :=. e) \quad s = (v \mapsto A \ e \ s) \ s$

$\text{ns } (s1 \ ; \ s2) \quad s = \text{ns } s2 \ (\text{ns } s1 \ s)$

$\text{ns } \text{Skip} \quad s = s$

$\text{ns } (\text{IF } c \ t \ e) \quad s \mid B \ c \ s = \text{ns } t \ s$

$\text{ns } (\text{IF } c \ t \ e) \quad s \mid \sim(B \ c \ s) = \text{ns } e \ s$

$\text{ns } (\text{While } c \ b) \ s \mid B \ c \ s = \text{ns } (\text{While } c \ b) \ (\text{ns } b \ s)$

$\text{ns } (\text{While } c \ b) \ s \mid \sim(B \ c \ s) = s$

note: alternatives are mutual exclusive, can be placed in any order

16

CEFP 2009: semantics

### how the type system helps us

- suppose we would write
 
$$\begin{aligned} \text{ns} &:: \text{Stmt State} \rightarrow \text{State} \\ \text{ns } (v :=. e) & \quad s = (v \mapsto e) s \\ \text{ns } (s1 \text{ .. } s2) & \quad s = \text{ns } s2 (\text{ns } s1 s) \\ \text{ns Skip} & \quad s = s \\ \dots \end{aligned}$$

this models lazy evaluation. It requires a state of type:  $\text{Var} \rightarrow \text{AExpr}$

- what is wrong with this?
- the type system says:
 

Type error [exprSem.icl,67,ns]:"argument 2 of |->" cannot unify types: Int AExpr
- we should have written:
 
$$\text{ns } (v :=. e) \quad s = (v \mapsto \text{A } e \text{ s}) s$$

17

CEFP 2009: semantics

### mathematical notation of semantic natural (big step) semantics

**Scott brackets**

$$\begin{aligned} \mathcal{NS} [ S_1 ; S_2 ] e \\ = \mathcal{NS} [ S_2 ] (\mathcal{NS} [ S_1 ] e) \end{aligned}$$

or

$$\begin{aligned} \mathcal{NS} [ S_1 ; S_2 ] \\ = \mathcal{NS} [ S_2 ] . \mathcal{NS} [ S_1 ] \end{aligned}$$

using Currying and function composition

these things do not have an order

**horizontal bars**

if the **premises** above the bar holds, the **conclusion** below it can be derived

$$\frac{\langle S_1, e \rangle \rightarrow e_1 \quad \langle S_2, e_1 \rangle \rightarrow e_3}{\langle S_1; S_2, e \rangle \rightarrow e_3}$$

using

$$\langle S, e \rangle \rightarrow e_1 \equiv \mathcal{NS} [ S ] e = e_1$$

18

CEFP 2009: semantics

### a small step operation semantics structural operational semantics

- one step a time
 
$$\begin{aligned} \text{Config} &= \text{Final State} \mid \text{Inter Stmt State} \\ \text{sos1} &:: \text{Stmt State} \rightarrow \text{Config} \\ \text{sos1 } (v :=. e) \text{ s} &= \text{Final } ((v \mapsto \text{A } e \text{ s}) s) \\ \text{sos1 Skip } s &= \text{Final } s \\ \text{sos1 } (x \text{ .. } y) \text{ s} \\ &= \text{case sos1 } x \text{ s of} \\ &\quad \text{Final } t = \text{Inter } y \text{ t} \\ &\quad \text{Inter } z \text{ t} = \text{Inter } (z \text{ .. } y) \text{ t} \\ \text{sos1 } (\text{IF } c \text{ t } e) \text{ s} \mid B \text{ c } s &= \text{Inter } t \text{ s} \\ \text{sos1 } (\text{IF } c \text{ t } e) \text{ s} \mid \sim(B \text{ c } s) &= \text{Inter } e \text{ s} \\ \text{sos1 } (\text{While } c \text{ b}) \text{ s} &= \text{Inter } (\text{IF } c \text{ (b .. While c b) Skip}) \text{ s} \end{aligned}$$

really different

20

CEFP 2009: semantics

### structural operational semantics 2

- trace obtained by applying **sos1** until a final state
 
$$\begin{aligned} \text{sosTrace} &:: \text{Config} \rightarrow [\text{Config}] \\ \text{sosTrace } c =: (\text{Final } \_) &= [c] \\ \text{sosTrace } c =: (\text{Inter } ss \text{ s}) &= [c: \text{sosTrace } (\text{sos1 } ss \text{ s})] \end{aligned}$$
- big step by selecting the last state of this trace
 
$$\begin{aligned} \text{sos} &:: \text{Stmt State} \rightarrow \text{State} \\ \text{sos } s \text{ env} &= \text{env1} \\ \text{where } (\text{Final } \text{env1}) &= \text{last } (\text{sosTrace } (\text{Inter } s \text{ env})) \end{aligned}$$

20

CEFP 2009: semantics

## denotational semantics

- we are interested in the final state, not how it is obtained

```

ds :: Stmt State -> State
ds (v :=. a) s = (v |-> A a s) s
ds Skip      s = s
ds (s1 ::. s2) s = ds s2 (ds s1 s)
ds (IF c t e) s = if (B c s) (ds t s) (ds e s)
ds (While c stmt) s = fix f s
where f g s = if (B c s) (g (ds stmt s)) s

```

```

fix :: (a -> a) -> a
fix f = f (fix f)

```

21

CEFP 2009: semantics

## main differences of the various semantics

- handling of the while-statement:
 

```

ns :: Stmt State -> State
ns (While c b) s | B c s = ns (While c b) (ns b s)
ns (While c b) s | ~ (B c s) = s

```

```

sos1 :: Stmt State -> Config
sos1 (While c b) s = Inter (IF c (b ::. While c b) Skip) s

```

```

ds :: Stmt State -> State
ds (While c stmt) s = fix f s
where f g s = if (B c s) (g (ds stmt s)) s

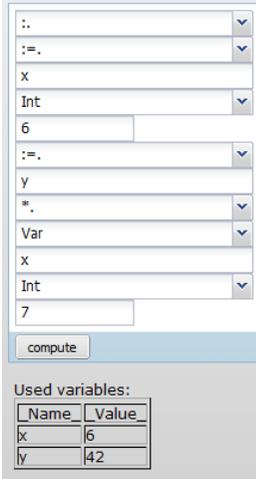

```

22

CEFP 2009: semantics

## simulation

- iData makes a syntax directed editor for statements
- any of the semantics can execute this program
- we scan the program for used variables and display their value
- useful for small experiments!
- demo

Name	Value
x	6
y	42

23

CEFP 2009: semantics

## testing properties

- Clean as its own model-based test tool: Gast
- we use this to test properties of the semantics
  - thousands of tests in a second
  - easy to repeat after each change
- this improves the confidence in the correctness
- if we have gathered enough confidence we can give a mathematical prove of these properties
  - even with a prove assistant this is usually much work

24

CEFP 2009: semantics

### some properties

```
propFac :: (Stmt State -> State) -> Bool
propFac sem = sem facStmt emptyState "y" == 24
```

$\forall \text{ sem}$

```
propFacAll :: Property
propFacAll = propFac For [ns, ds, sos ]
```

$\forall \text{ sem} \in \{ \text{ns, ds, sos} \}$

$\forall \text{ statement}$

```
prop :: Stmt -> Bool
prop s = eqState (ns s empty) (ds s empty) (allvars s)
```

checks equality for given variables

generate only terminating statements

25

CEFP 2009: semantics

### wrap up: main idea

- semantics  $\approx$  interpreter that focuses on clarity rather than efficiency

CEFP 2009: semantics

### lessons learned

- semantics assigns meaning to languages
  - natural semantics: shows how the value is computed in big steps
  - structural operational semantics: small steps
  - denotational semantics: concentrate on the value
- with very little effort this can be expressed in a modern functional programming language
- advantages:
  - checks use of identifiers and types
  - simulate language for validation
  - model based testing of properties
- warning: there is much more in semantics

27

CEFP 2009: semantics

### exercise

- purpose: get acquired with iTasks and this style of semantics
- see <http://www.cs.ru.nl/~pieter/cefp09/>
  - exercise as pdf
  - Clean files for parts 5 and 6.

28
